

# Improving responsiveness of interactive CFS tasks using util\_est

*Monday, 20 September 2021 10:20 (30 minutes)*

One of the most significant metrics for good user experience on a mobile device is how quickly the system can react to load changes.

Util\_est is used in mainline to create a more stable signal for per-task demand, which is the maximum of the task util\_est and PELT utilization (known as the task utilization).

In case PELT utilization becomes higher than util\_est, the behaviour of that task is changing and it needs more resources than previously allocated. The responsiveness of the task can be improved by boosting the task utilization during this time beyond its PELT utilization.

This presentation describes an implementation of this idea and shows how it improves behaviour on an Android device.
