#### About Me

Hi, I'm Omid

Twitter: @oazizi Principal engineer at New Relic. Founding engineer at Pixie Labs (@pixie\_run)

**ה** 

#### Introduction

In 2019, we set out to build a no-instrumentation observability platform.

- Our Vision: Help developers understand and debug their K8s apps.

First goal: Trace application network messages.

- HTTP, then other protocols.

user user-db with front-end catalog catalog-db

We had two key requirements:

(1) **No instrumentation**: No code modifications, no redeployments.

(2) Low overhead: Always active.

#### Overview

No instrumentation + low overhead ⇒ **eBPF**.

General approach:

- Capture data in kernel-space with eBPF.
- Process data in user-space (protocol parsing).
- Store data into tables for querying by user.

# Building a Protocol Tracer

# Where to Trace the Data?

Many options in the software stack:

We preferred tracing as close to the application layer as possible.

# Approaches Compared

	protocol library uprobes	syscall kprobes	libpcap/XDP
Tracing overhead	Low	Low	Low
Scalability & Stability	Uprobes per library, Probe targets may change	High	High
Parsing effort	None	Protocol parsing	Packet processing & protocol parsing
SSL tracing	Cleartext available	Data encrypted	Data encrypted

We chose to use syscall kprobes on functions such as send() & recv().

Rationale: close to the application layer, but stable API.

# Performance Overhead

Production servers are typically in this range, since they do real work.

Study: Deploy probes on an HTTP server.

- X-axis: the amount of work performed by the per request.

Take-away: kprobe overhead < 2% overhead as long as server is not trivial.

## Framework and Requirements

The Pixie data collector (Stirling) is written in C++

- Uses both BCC and BPFTrace for eBPF
- The protocol tracer uses BCC for the greater degree of control.

Requirements

- Need to support older kernels: we don't control the target ecosystem.
- Minimum kernel version supported: 4.14

Restrictions

- 4096 instruction limit :(
- No ringbuf :(
- Really want to use libbpf + CO-RE..but we can't :(

#### 1 - Setup probes on network related syscalls.

#### 2 - Record connection metadata in BPF maps.

**1** 

3 - Infer protocol with basic rule-based classification as a simple filter. Transfer connection information and data through two perf buffers.

4 - Track connections in user-space with ConnTrackers. Parse ConnTracker data into structured messages.

# So, it all just works...right?

The general approach of tracing syscalls has some benefits

- Avoided the complexity of the network layer.
- Easy correlation of events to PID

But the approach is not without its challenges, including:

- Dealing with the variety of syscalls.
- Finding the remote endpoint address.
- Implementing protocol inference in eBPF.
- Dealing with stateful protocols (HTTP/2) and encrypted traffic (TLS).

# Challenges of Tracing Syscalls

Tracing syscalls is a double-edged sword.

- Benefit: The stable API makes our probes portable across kernel versions.
- Con: Over the years, many ways of doing the same thing have evolved.
  - We have to account for all of them.

The protocol tracer probes a total of 17 Linux syscalls.

# List of Syscalls

Connection management	Recv variants	Write variants	Special purpose
connect accept accept4 close	read readv recv recvfrom recvmsg recvmmsg	write writev send sendto sendmsg sendmsg sendfile	sock_alloc sock_sendmsg sock_recvmsg

# Challenges of Tracing Syscalls: Examples

Example	Problem	Our Solution
<b>read &amp; write</b> syscalls are used for both file I/O and sockets.	When we trace these syscalls, we end up with more than network traffic.	Trace <b>sock_sendmsg</b> & <b>sock_recvmsg</b> to select only the socket traffic.
accept may be called with a NULL addr argument.	When NULL, the remote endpoint address is not directly accessible.	Trace internal <b>sock_alloc</b> calls to figure out missing address.
Variants like <b>sendmsg</b> & <b>recvmsg</b> have multiple data chunks.	BPF doesn't support loops.	Unrolled loop over a bounded number of chunks (45). Lose data beyond that.

# Challenges of Tracing Mid-Stream

As an observability tool, we may not see the entire connection stream.

Problem for long-lived streams: we won't know the remote endpoint.

- So we resolve endpoints from user-space.

### eBPF-Side Protocol Inference

To filter data transfers to user-space, we apply protocol inference in BPF.

- Just a filter: False positives are okay.
- Example for HTTP:

static \_\_inline enum MessageType infer\_http\_message(const char\*
buf, size\_t count) {
 ...
 if (buf[0] == 'H' && buf[1] == 'T' && buf[2] == 'T' && buf[3] == 'P') {
 return kResponse;
 }
 ...

# Likelihood that our inference eventually identifies the right protocol

# Pluggable Protocol Parsers

Architecture consists of pluggable protocol parsers

\*gRPC is traced with dedicated uprobes

We are working on making it easier to contribute protocols

Including a contribution guide

# When kprobes are not enough: Tracing gRPC and TLS

# Tracing HTTP/2 and gRPC: The problem

The kprobe-based approach has been mostly effective, but...

- HTTP/2 includes a *stateful* compression scheme called HPACK.
- HPACK uses a dynamic dictionary of common header values.
- We can't decode the headers if we don't have the dictionary.

# Tracing HTTP/2 and gRPC: What to do?

Unfortunately, we can't count on knowing the dictionary.

- We may deploy after the HTTP/2 connection was made
- We may lose data through the perf buffer.

Options we considered:

3)

- 1) Try to learn the dictionary.
  - Tried it. Too complex..
- 2) Recover the dictionary state via uprobes.
  - No easy place to probe.
  - Trace the gRPC library directly via uprobes.
    - Not easy, but our only viable option.

# Tracing gRPC: Our Approach

Use uprobes to capture data before it's compressed.

We have implemented uprobes for Golang's gRPC library; other libraries are planned.

# Our gRPC Experience: Takeaways

Any protocol that is stateful is hard to decode.

- Compression on individual messages is okay; problem is with dependent state.
- Tools like tWireshark face the same issue: can't decode headers without the state.

The uprobe based approach is hindered by the scalability problem.

- We need uprobes for each gRPC library for full tracing.
- Must take care to place uprobes on functions that appear stable across versions.
- Need debug symbols to make it more robust

# Making Uprobes Robust

Read DWARF information to find offsets; pass them to the BPF program.

```
int probe http2 framer write data(struct pt reqs* ctx) {
uint32 t tgid = bpf get current pid tgid() >>32;
struct qo http2 symaddrs t* symaddrs = http2 symaddrs map.lookup(&tgid)
if (symaddrs == NULL) {
REQUIRE SYMADDR(symaddrs->http2 WriteDataPadded f offset 0);
REQUIRE SYMADDR(symaddrs->http2 WriteDataPadded streamID offset 0);
REQUIRE SYMADDR(symaddrs->http2 WriteDataPadded endStream offset 0);
REQUIRE SYMADDR(symaddrs->http2 WriteDataPadded data offset 0);
void* framer ptr;
```

# SSL Tracing

Tracing SSL traffic with kprobes doesn't work either.

- Data is already encrypted

Uprobes come to the rescue

- Trace the SSL library instead

BCC has a similar tool: sslsniff

# Uprobes on TLS Libraries

There is a simple mapping of kprobes to uprobes

Kprobe function	OpenSSL API function	Golang crypto/tls library
read/recv	SSL_read	crypto/tls.(*Conn).Read
write/send	SSL_write	crypto/tls.(*Conn).Write

Uprobes on SSL API push to same perf buffer as syscall probes

- No changes to user-space code :)

# SSL Tracing Observations

While uprobes have the scalability problem, it's not so bad with SSL

- The number of popular SSL libraries is small.
- By tracing a public API, we get good probe stability across versions.

One interesting exception: node.js

- Uses OpenSSL in an asynchronous manner (via libuv).
- Makes it hard to correlate the traced data with a FD.

Requires additional node.js specific uprobes :(

# Summary

Pixie is a Kubernetes observability platform.

- Protocol tracer provides instant visibility on K8s clusters.
- No user instrumentation: powered by eBPF.

Pixie is now an open-source CNCF sandbox project

- https://github.com/pixie-io/pixie
- Contributions are welcome!
