Linaro

Problem Statement

- Delay in propagating signals from input elements to output elements in a circuit path cannot exceed the time period between synchronizing clock pulses.
- > If the delay is greater than a clock cycle, the circuit will not function as expected.
- SoCs are characterized for timing closure in a temperature range.
- > At lower temperatures, certain voltage and frequency combination CANNOT meet timing closure.
- Leads to non-functional system under extremely cold temperatures (< 0 degree Celsius)</p>
- \succ To close timing, the operating voltage must be increased.
- > Opposite of what is required to cool down the system.

Proposed Solution

- Linux Kernel Thermal Management
 Framework already has provision to monitor and handle out of bounds temperature.
- Extend the framework to monitor and handle falling temperature.
- > Two requirements
 - Thermal framework should monitor and handle descending temperature.
 - Thermal framework should support warming devices

Proposed Solution Cont..

| | TRIP POINTS | THERMAL GOVERNOR | WARMING DEVICES |
|----|--|--|--|
| - | Support for cold trip points. | Support for monitoring and mitigating falling | Software based warming mechanisms (genod based |
| - | New trip type: THERMAL_TRIP_COLD | temperature (triggering warming action) | warming mechanism[2], disabling lower operating points of devices) |
| - | "cold": trip point property in dt | New range governor vs extending existing governors ? | Resource specific warming mechanisms[3] |
| - | Enable notification mechanism via netlink interface. | | 2. https://lkml.org/lkml/2020/6/3/1112 |
